Cells, biological circuits, and individual biomolecules organize themselves and interact with the environment. Use of these capabilities in flexible and economically efficient biotechnological production systems is in the focus of the “Molecular Interaction Engineering” (MIE) project. It is the objective to develop printed biological circuits and catalysts for biologicotechnical hybrid systems. MIE will be funded with about EUR 3.5 million by the BMBF.

The capabilities of biological systems are based on specific interactions of molecular components. Due to their molecular fitting accuracy, for instance, enzymes allow for certain chemical reactions only. Some proteins bind via specific molecular interfaces to the DNA or other proteins and control processes in complex organisms. Sensors respond to defined molecular signals from the environment. The MIE project focuses on interactions of molecules, technical interfaces, and surrounding solvents.

“Transfer of complex biological mechanisms to printable systems may result in innovative biotechnologies that might be the basis of a number of industrial applications,” Professor Jürgen Hubbuch, project coordinator at KIT, explains. However, conventional, continuous evolution of biological molecules reaches its limits. The key to innovative developments is the specific, adjusted construction of the interaction of complex biomolecules and fusion of these units with technical interfaces. This requires close cooperation of biology, engineering, chemistry, and physics.

The “Molecular Interaction Engineering” (MIE) project combines methods of biotechnology, structural biology, materials sciences, process engineering, and computer simulation. Work is aimed at developing innovative, flexible, and economically efficient biotechnological production systems for molecules. These might then be used in biohybrid systems integrating biological and electronic components. Biohybrid systems allow for new applications in food technology, molecular biology, medical diagnostics, and pharmaceutical industry.

KIT’s Institute of Process Engineering in Life Sciences (BLT), the Institute of Functional Interfaces (IFG), the Institute of Microstructure Technology (IMT), the Institute of Nanotechnology (INT), the Institute of Toxicology and Genetics (ITG), the Institute of Thermal Process Engineering – Thin Film Technology (TVT-TFT), and the KIT Young Investigator Group “Biohybrid Nanoarrays for Biotechnological and Biomedical Applications” participate in MIE. In 2013, the project is funded with about EUR 3.5 million by the Federal Ministry of Education and Research (BMBF) for a period of five years. A second funding package of EUR 1.6 million has been announced for 2014.

The MIE Helmholtz Research Network was initiated by KIT, Forschungszentrum Jülich

(FZJ), and Helmholtz-Zentrum Geesthacht (HZG) under the Biotechnology 2020+ strategy process of BMBF. The research network is one of four large-scale projects of the four large German non-university research organizations (Fraunhofer Society, Helmholtz Association, Leibniz Association, Max Planck Society) that are to be funded under the Biotechnology 2020+ initiative. Within the framework of the above strategy process, German research organizations agreed on a memorandum of understanding for the interdisciplinary development of a next generation of biotechnological processes.
